ABSTRACT

Recent studies on sustainable urban paving solutions have focused on the use of permeable pavements and the integration of recycled materials, such as construction and demolition (C&D) waste. As urbanization increases, vegetated areas are being replaced by impermeable surfaces, causing negative impacts such as higher surface runoff and reduced water infiltration. Permeable pavements provide an efficient alternative, allowing water infiltration into the soil and contributing to flood mitigation and aquifer recharge. The use of recycled aggregates, such as recycled concrete and reclaimed asphalt, has gained attention because it reduces the demand for natural materials and minimizes the environmental impact of construction. However, the application of these materials still faces challenges, such as the variability of recycled waste, resistance issues, and the risk of pore clogging, which can impair long-term infiltration capacity. Recent studies indicate that the mechanical properties and durability of these pavements can be improved through techniques such as chemical stabilization and resin treatments. The lack of clear technical regulations and concrete economic data has limited the large-scale implementation of these systems, but ongoing research is helping to overcome these barriers. Standardizing testing methods, defining performance criteria, and establishing proper maintenance guidelines are crucial steps to ensure the widespread adoption of these solutions. Ultimately, the use of permeable pavements with recycled materials represents an effective strategy for promoting urban sustainability, reducing the environmental impact of construction, and improving the quality of life in cities.

Keywords: Permeable pavements. Material recycling. Construction and demolition waste. Urban sustainability. Water infiltration.

INTRODUCTION

In recent years, urbanization and its associated environmental impacts, such as soil impermeabilization, have prompted the search for more sustainable civil engineering solutions. Among the promising alternatives, permeable pavements have gained attention for their ability to allow water infiltration, which reduces runoff and supports aquifer recharge. At the same time, the increasing generation of construction and demolition waste (CDW) has spurred the development of techniques aimed at reusing these materials, especially in urban infrastructure. The integration of CDW into the construction of permeable pavements represents a convergence of these two sustainable approaches. Various studies have examined the use of recycled aggregates, such as recycled concrete aggregate (RCA), crushed brick (CB), and reclaimed asphalt pavement (RAP), in different pavement layers, including subgrades, sub-bases, and stabilized bases. These studies demonstrate that, with appropriate treatments like lime, cement, or resin applications, the mechanical properties, water stability, and durability of pavements containing CDW can be significantly enhanced.

However, challenges remain, particularly with the variability in recycled waste composition, lower abrasion resistance, and the risk of pore clogging, which can hinder long-term infiltration capacity. Additionally, there is a lack of standardized technical guidelines for the use of CDW in permeable pavements, limiting widespread adoption. To facilitate broader implementation, establishing standardized testing methods,

performance criteria, and maintenance protocols is essential. Despite these barriers, the literature suggests that combining permeable pavements with the reuse of demolition materials offers an effective strategy for advancing urban sustainability. With proper quality control and the application of modification technologies, it is possible to create environmentally responsible and feasible solutions for the pavement industry.

Pereira and Vieira (2022) explore the potential of using construction and demolition (C&D) waste in the construction industry, specifically focusing on unbound road pavement applications. They emphasize that the construction sector's significant environmental footprint—due to its high energy consumption, resource use, and waste generation—calls for effective waste management and recycling strategies. The study advocates for the use of recycled aggregates from C&D waste as a sustainable solution for pavement layers, showing that these materials can be both economically viable and environmentally beneficial. A comparison of the mechanical properties of recycled aggregates versus natural aggregates highlights the long-term performance of the former in unbound pavement applications. Furthermore, the research provides an overview of C&D waste generation and recovery practices in the European Union, reinforcing the need for scientific validation of the technical and environmental benefits of using recycled materials in pavements.

The study by Salehi et al. (2021) discusses the challenges and opportunities linked to replacing virgin materials with recycled materials in pavement construction, aiming to reduce the environmental impacts of waste from municipal, commercial, industrial, and construction sectors. While this substitution offers significant potential for waste management and sustainability goals, uncertainties remain regarding the economic and environmental implications of using recycled materials. The research reviews the performance of various materials, including recycled concrete aggregates, lignin, recycled plastic, crushed glass, crushed brick, and crumb rubber, noting that sustainability analyses of these materials are still in the early stages. Inconsistencies in methodologies complicate cross-study comparisons, and the lack of attention to maintenance, usage, and end-of-life phases in life cycle assessments undermines the evaluation of long-term viability. The study emphasizes the need for more research to provide deeper insights into the impacts of recycled materials, enabling informed decision-making by policymakers.

Xie, Akin, and Shi (2019) offer an in-depth review of the state of knowledge on permeable concrete pavements (PCPs), with a focus on improving their overall performance and maximizing environmental benefits. PCPs provide several environmental advantages, including reducing stormwater runoff, improving groundwater quality, mitigating urban heat islands, reducing traffic noise, and enhancing skid resistance. However, the hydraulic performance of these pavements is influenced by factors such as mix design, pavement structure, construction practices, and service conditions. One major challenge is balancing the mechanical properties, durability, and infiltration capacity of these systems. The study highlights the need for new technologies that enhance the durability of PCPs without compromising their infiltration ability or increasing maintenance costs. Challenges such as freeze-thaw damage, deicer effects, and clogging still hinder the widespread use of this technology. The authors call for more precise material characterizations and better understanding of the correlations between physicochemical properties and performance. Additionally, emerging fields such as nanotechnology could offer innovative solutions to enhance the durability and environmental benefits of permeable pavements.

Mohanty, Mohapatra, and Nayak (2022) provide a systematic review of the use of construction and demolition (C&D) waste as aggregate in the base and subbase layers of pavements. They highlight the environmental issues associated with C&D waste, such as land consumption, landfill depletion, and pollution, and emphasize the potential of using these materials in pavement construction. The study evaluates the mechanical and durability performance of C&D waste in both bound and unbound applications, revealing that properties like California Bearing Ratio (CBR) and Unconfined Compressive Strength (UCS) decrease as waste content increases. However, chemical stabilization can improve these properties. The research also indicates that the resilient modulus of treated C&D materials improves with higher stabilizer content, longer curing times, and increased confining pressure. The study further identifies the need for exploring other waste types for use in base or subbase layers and provides valuable insights that can guide the adoption of non-traditional aggregates in pavement construction, contributing to more sustainable construction practices.

Sambito et al. (2021) conducted a comprehensive review of the hydrological and environmental performance of permeable pavement systems, with a focus on urban drainage and durability. They point out that urbanization has led to the replacement of

vegetated areas with impermeable surfaces, resulting in increased surface runoff, reduced soil water infiltration, and lower evapotranspiration. Permeable pavements offer a solution by allowing water to infiltrate the ground, thus mitigating hydrological impacts. The study reviews methods used to assess the performance of these systems, including their efficiency in removing conventional pollutants and their broader environmental impacts. The literature survey, which analyzed 1,238 articles, identified 17 studies that met the inclusion criteria. The findings offer critical insights that advance understanding of the environmental benefits of permeable pavements and suggest directions for future research in this field.

Kuruppu, Rahman, and Rahman (2019) reviewed the current state of permeable pavement research, focusing on the limitations of its applicability. The paper discusses the impact of various design factors such as pavement type, mix design, aggregate materials, and sub-base depth on hydraulic, structural, and environmental performance. Despite the potential of permeable pavements, their adoption has been slow, primarily due to a lack of scientific understanding and economic uncertainties. The study stresses the importance of further research to address these gaps and suggests several challenges for future investigation, including the unavailability of cost data, difficulties in estimating intangible benefits, and the need for design modifications that optimize environmental, hydraulic, and structural performance. The authors also highlight the challenges of simulating real-world conditions in laboratory experiments, developing standardized maintenance procedures, and improving the bearing capacity of pavements to withstand higher traffic loads.

The use of permeable pavements, especially those incorporating construction and demolition (C&D) recycled materials, has proven to be a promising solution to address urban environmental challenges. The increase in urbanization and soil impermeabilization has caused significant impacts, such as increased surface runoff and reduced water infiltration into the soil. Permeable pavements allow water infiltration, contributing to aquifer recharge and mitigating flooding. Additionally, the reuse of recycled aggregates, such as recycled concrete and reclaimed asphalt, not only reduces the environmental impact of natural resource extraction but also provides a more sustainable and economical alternative in pavement construction. However, challenges such as the variability of recycled waste and the lack of specific technical regulations still limit the widespread adoption of these solutions.

Advances in research and the implementation of modification technologies, such as chemical stabilization and the use of resins, have shown that it is possible to improve the mechanical properties and durability of pavements made with recycled materials, allowing for greater environmental and structural efficiency. Despite existing limitations, such as the difficulty of simulating real-field conditions and the lack of concrete economic data, the future of permeable pavements integrated with recycled materials looks promising. With further research, standardization of testing methods, and clear maintenance guidelines, these solutions have the potential to become essential practices for promoting urban sustainability, helping to reduce the construction industry's ecological footprint and improving the environmental quality of cities.
